# Module 8 Case Studies in Longitudinal Data Analysis

**Benjamin French**, PhD Radiation Effects Research Foundation University of Pennsylvania

> SISCR 2017 July 25, 2017

## Learning objectives

- This module will focus on the design of longitudinal studies, exploratory data analysis, and application of regression techniques based on estimating equations and mixed-effects models
- Case studies will be used to discuss analysis strategies, the application of appropriate analysis methods, and the interpretation of results, with examples in R and Stata
- Some theoretical background and details will be provided; our goal is to translate statistical theory into practical application
- At the conclusion of this module, you should be able to apply appropriate exploratory and regression techniques to summarize and generate inference from longitudinal data

#### Overview

Review: Longitudinal data analysis

Case study: Longitudinal depression scores

Case study: Indonesian Children's Health Study

Case study: Carpal tunnel syndrome

Summary and resources

#### Overview

Review: Longitudinal data analysis

Case study: Longitudinal depression scores

Case study: Indonesian Children's Health Study

Case study: Carpal tunnel syndrome

Summary and resources

## Longitudinal studies

Repeatedly collect information on the same individuals over time

#### **Benefits**

- Record incident events
- Ascertain exposure prospectively
- Separate time effects: cohort, period, age
- Distinguish changes over time within individuals
- Offer attractive efficiency gains over cross-sectional studies
- Help establish causal effect of exposure on outcome

## Longitudinal studies

Repeatedly collect information on the same individuals over time

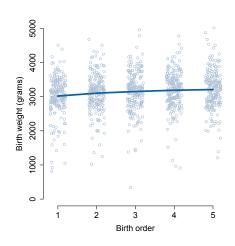

#### Challenges

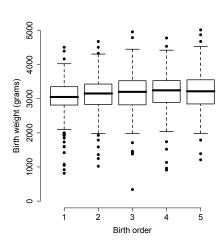

- Determine causality when covariates vary over time
- Choose exposure lag when covariates vary over time
- Account for incomplete participant follow-up
- Use specialized methods that account for longitudinal correlation

#### Georgian infant birth weight

- Birth weight measured for each of m = 5 children of n = 200 mothers
- ullet Birth weight for infants j comprise repeated measures on mothers i
- · Interested in the association between birth order and birth weight
  - Estimate the average time course among all mothers
  - Estimate the time course for individual mothers
  - Quantify the degree of heterogeneity across mothers
- Consider adjustment for mother's initial age (at first birth)

		${\tt momid}$	${\tt birthord}$	bweight	lowbrth	initage
[	[1]	39	1	3720	0	15
[	[2]	39	2	3260	0	15
[	[3]	39	3	3910	0	15
	[4]	39	4	3320	0	15
	[5]	39	5	2480	1	15
[	[6]	62	1	2381	1	17
[	[7]	62	2	2835	1	17
[	[8]	62	3	2381	1	17
[	[9]	62	4	2268	1	17
[1	[0]	62	5	2211	1	17

## Strategies for analysis of longitudinal data

• **Derived variable**: Collapse the longitudinal series for each subject into a summary statistic, such as a difference (a.k.a. "change score") or regression coefficient, and use methods for independent data

 Repeated measures: Include all data in a regression model for the mean response and account for longitudinal and/or cluster correlation

## Options for analysis of change

#### Does mean change differ across groups?

- Consider simple situation with
  - ▶ Baseline measurement (t = 0)
  - ▶ Single follow-up measurement (t = 1)
- · Analysis options for simple pre-post design
  - Analysis of POST only
  - Analysis of CHANGE (post-pre)
  - Analysis of POST controlling for BASELINE
  - Analysis of CHANGE controlling for BASELINE

## Change and randomized studies

- Key assumption: groups equivalent at baseline
- Methods that 'adjust' for baseline are generally preferable due to greater precision
  - ho > 1/2 POST  $\prec$  CHANGE  $\prec$  ANCOVA
  - ho < 1/2 CHANGE  $\prec$  POST  $\prec$  ANCOVA
  - ► CHANGE analysis adjusts for baseline by subtracting it from follow-up
  - ▶ ANCOVA analysis adjusts for baseline by controlling for it in a model
- Missing data will impact each approach

## Change and non-randomized studies

- Baseline equivalence no longer guaranteed
- Methods no longer answer same scientific question
  - POST: How different are groups at follow-up?
  - ► CHANGE: How different is the change in outcome for the two groups?
  - ANCOVA: What is the expected difference in the mean outcome at follow-up across the two groups, controlling for the baseline value of the outcome?
- CHANGE typically most relevant; multivariable methods to come later characterize CHANGE across multiple timepoints

## Strategies for analysis of longitudinal data

- Derived variable: Collapse the longitudinal series for each subject into a summary statistic, such as a difference (a.k.a. "change score") or regression coefficient, and use methods for independent data
  - ▶ Example: birth weight of 2nd child birth weight of 1st child
  - Might be adequate for two time points and no missing data
- Repeated measures: Include all data in a regression model for the mean response and account for longitudinal and/or cluster correlation
  - ► Generalized estimating equations (GEE)

► Generalized linear mixed-effects models (GLMM)

#### **Notation**

## Define

$$m_i = \text{number of observations for subject } i = 1, ..., n$$
 $Y_{ij} = \text{outcome for subject } i \text{ at time } j = 1, ..., m_i$ 
 $X_i = (x_{i1}, x_{i2}, ..., x_{im_i})$ 
 $x_{ij} = (x_{ij1}, x_{ij2}, ..., x_{ijp})$ 
exposure, covariates

#### Stacks of data for each subject:

$$Y_{i} = \begin{bmatrix} Y_{i1} \\ Y_{i2} \\ \vdots \\ Y_{im_{i}} \end{bmatrix} \qquad X_{i} = \begin{bmatrix} x_{i11} & x_{i12} & \dots & x_{i1p} \\ x_{i21} & x_{i22} & \dots & x_{i2p} \\ \vdots & \vdots & \vdots & \vdots \\ x_{im_{i}1} & x_{im_{i}2} & \dots & x_{im_{i}p} \end{bmatrix}$$

## Dependence and correlation

Issue | Response variables measured on the same subject are correlated

- Observations are dependent or correlated when one variable predicts the value of another variable
  - ► The birth weight for a first child is predictive of the birth weight for a second child born to the same mother
- Variance: measures average distance that an observation falls away from the mean
- Covariance: measures whether, on average, departures in one variable  $Y_{ij}-\mu_j$  'go together with' departures in another variable  $Y_{ik}-\mu_k$
- ullet Correlation: measure of dependence that takes values from -1 to +1

## Covariance: Something new to model

$$\mathsf{Cov}(Y_{i}) = \begin{bmatrix} \mathsf{Var}(Y_{i1}) & \mathsf{Cov}(Y_{i1}, Y_{i2}) & \dots & \mathsf{Cov}(Y_{i1}, Y_{im_{i}}) \\ \mathsf{Cov}(Y_{i2}, Y_{i1}) & \mathsf{Var}(Y_{i2}) & \dots & \mathsf{Cov}(Y_{i2}, Y_{im_{i}}) \\ \vdots & \vdots & \vdots & \vdots \\ \mathsf{Cov}(Y_{im_{i}}, Y_{i1}) & \mathsf{Cov}(Y_{im_{i}}, Y_{i2}) & \dots & \mathsf{Var}(Y_{im_{i}}) \end{bmatrix}$$

$$= \begin{bmatrix} \sigma_{1}^{2} & \sigma_{1}\sigma_{2}\rho_{12} & \dots & \sigma_{1}\sigma_{m_{i}}\rho_{1m_{i}} \\ \sigma_{2}\sigma_{1}\rho_{21} & \sigma_{2}^{2} & \dots & \sigma_{2}\sigma_{m_{i}}\rho_{2m_{i}} \\ \vdots & \vdots & \vdots & \vdots \\ \sigma_{m_{i}}\sigma_{1}\rho_{m_{i}1} & \sigma_{m_{i}}\sigma_{2}\rho_{m_{i}2} & \dots & \sigma_{m_{i}}^{2} \end{bmatrix}$$

Note:  $\rho = \text{correlation}$ 

# GEE (Liang and Zeger, 1986)

- ★ Contrast average outcome values across **populations** of individuals defined by covariate values, while accounting for correlation
  - Focus on a generalized linear model with regression parameters  $\beta$ , which characterize the systemic variation in  $\boldsymbol{Y}$  across covariates  $\boldsymbol{X}$

$$Y_i = (Y_{i1}, Y_{i2}, ..., Y_{im_i})^T$$
  
 $X_i = (x_{i1}, x_{i2}, ..., x_{im_i})^T$   
 $x_{ij} = (x_{ij1}, x_{ij2}, ..., x_{ijp})$   
 $\beta = (\beta_1, \beta_2, ..., \beta_p)^T$ 

for 
$$i = 1, ..., n$$
;  $j = 1, ..., m_i$ ; and  $k = 1, ..., p$ 

• Longitudinal correlation structure is a nuisance feature of the data

#### Mean model

#### **Assumptions**

- Observations are independent across subjects
- Observations could be correlated within subjects

Mean model: Primary focus of the analysis

$$E[Y_{ij} \mid x_{ij}] = \mu_{ij}(\beta)$$
$$g(\mu_{ij}) = x_{ij}\beta$$

• Corresponds to any generalized linear model with link  $g(\cdot)$ 

Continuous out	come	Count outcome			Binary outcome		
$E[Y_{ij} \mid x_{ij}] =$	$\mu_{ij}$	$E[Y_{ij} \mid x_{ij}]$	=	$\mu_{ij}$	$P[Y_{ij} = 1 \mid x_{ij}]$	=	$\mu_{ij}$
$\mu_{ij} =$	$x_{ij}eta$	$log(\mu_{ij})$	=	$x_{ij}eta$	$logit(\mu_{ij})$	=	$x_{ij}eta$

• Characterizes a marginal mean regression model

#### Covariance model

Longitudinal correlation is a nuisance; secondary to mean model of interest

1. Assume a form for **variance** that could depend on  $\mu_{ij}$ 

Continuous outcome: 
$$Var[Y_{ij} \mid x_{ij}] = \sigma^2$$
  
Count outcome:  $Var[Y_{ij} \mid x_{ij}] = \mu_{ij}$   
Binary outcome:  $Var[Y_{ij} \mid x_{ij}] = \mu_{ij}(1 - \mu_{ij})$ 

which could also include a scale or dispersion parameter  $\phi>0$ 

2. Select a model for longitudinal **correlation** with parameters  $\alpha$ 

Independence:  $\operatorname{Corr}[Y_{ij},Y_{ij'}\mid X_i]=0$  Exchangeable:  $\operatorname{Corr}[Y_{ij},Y_{ij'}\mid X_i]=\alpha$  Auto-regressive:  $\operatorname{Corr}[Y_{ij},Y_{ij'}\mid X_i]=\alpha^{|j-j'|}$  Unstructured:  $\operatorname{Corr}[Y_{ij},Y_{ij'}\mid X_i]=\alpha_{jj'}$ 

#### Intuition

$$0 = \sum_{i=1}^{n} \underbrace{D_{i}^{\mathsf{T}}}_{3} \underbrace{V_{i}^{-1}}_{2} \underbrace{(Y_{i} - \hat{\mu}_{i})}_{1}$$

- 1 The model for the mean,  $\mu_i(\beta)$ , is compared to the observed data,  $Y_i$ ; setting the equations to equal 0 tries to minimize the difference between **observed** and **expected**
- 2 Estimation uses the inverse of the variance (covariance) to **weight** the data from subject *i*; more weight is given to differences between observed and expected for subjects who contribute more information
- 3 Simply a "change of scale" from the scale of the mean,  $\mu_i$ , to the scale of the regression coefficients (covariates)

#### Comments

- GEE is specified by a mean model and a correlation model
  - 1. A regression model for the average outcome, e.g., linear, logistic
  - 2. A model for longitudinal correlation, e.g., independence, exchangeable
- $\hat{\beta}$  is a consistent estimator for  $\beta$  provided that the mean model is correctly specified, even if the model for longitudinal correlation is incorrectly specified, i.e.,  $\hat{\beta}$  is 'robust' to correlation model mis-specification
- However, the variance of  $\hat{\beta}$  must capture the correlation in the data, either by choosing the correct correlation model, or via an alternative variance estimator
- GEE computes a sandwich variance estimator (aka empirical, robust, or Huber-White variance estimator)
- Empirical variance estimator provides valid standard errors for  $\hat{\beta}$  even if the working correlation model is incorrect, but requires  $n \geq 40$  (Mancl and DeRouen, 2001)

#### Variance estimators

- **Independence estimating equation**: An estimation equation with a working independence correlation structure
  - Model-based standard errors are generally not valid
  - ▶ Empirical standard errors are valid given large n and  $n \gg m$
- Weighted estimation equation: An estimation equation with a non-independence working correlation structure
  - Model-based standard errors are valid if correlation model is correct
  - ▶ Empirical standard errors are valid given large n and  $n \gg m$

	Variance estimator				
Estimating equation	Model-based	Empirical			
Independence	_	+/-			
Weighted	-/+	+			

#### GEE commands

- Stata: xtset, then use xtgee
- R: geeglm in geepack library, using geese fitter function
- SAS: PROC GENMOD
- NB: Order might be important for analysis in software
  - Requires sorting the data by unique subject identifier and time
  - ▶ Important for exchangeable and auto-regressive correlation structures

Interested in the association between birth order and birth weight

$$\mathsf{E}[Y_{ij} \mid x_{ij}] = \beta_0 + \beta_1 x_{ij1} + \beta_2 x_{ij2}$$

for  $i = 1, \dots, 200$  and  $j = 1, \dots, 5$  with

- Yij: Infant birth weight (continuous)
- $x_{ij1}$ : Infant birth order
- $x_{ij2}$ : Mother's initial age

## Motivating example: Stata commands

- \* Declare the dataset to be "panel" data, grouped by momid
- \* with time variable birthord xtset momid birthord
- \* Fit a linear model with independence correlation xtgee bweight birthord initage, corr(ind) robust
- \* Fit a linear model with exchangeable correlation xtgee bweight birthord initage, corr(exc) robust

## Motivating example: Stata output

```
Number of obs =
GEE population-averaged model
                                                           1000
Group variable:
                             momid
                                      Number of groups =
                                                          200
Link:
                           identity
                                      Obs per group: min =
Family:
                           Gaussian
                                                  avg = 5.0
Correlation:
                        independent
                                                  max =

   cons | 2526.622 177.2781 14.25 0.000 2179.164 2874.081
```

## Motivating example: Comments

- Difference in mean birth weight between two populations of infants whose birth order differs by one is 46.6 grams, 95% CI: (27.0, 66.2)
- Model-based standard errors are smaller for exchangeable structure, indicating efficiency gain from assuming a correct correlation structure
- In practice, i.e. with real-world data, it's often difficult to tell what the correct correlation structure is from exploratory analyses
- A priori scientific knowledge should ultimately guide the decision
- I tend to use working independence with empirical standard errors unless I have a good reason to do otherwise, e.g. large efficiency gain
- ullet Try not to select the structure that gives you the smallest p-value
- Stata labels the standard errors "semi-robust" because the empirical variance estimator protects against mis-specification of the correlation model, but requires correct specification of the mean model
- ★ See help xtgee for detailed syntax, other options, and saved results

## **GEE** summary

- In the GEE approach the primary focus of the analysis is a marginal mean regression model that corresponds to any GLM
- Longitudinal correlation is secondary to the mean model of interest and is treated as a nuisance feature of the data
- Requires selection of a 'working' correlation model
- Semi-parametric: Only the mean and correlation models are specified
- The correlation model does not need to be correctly specified to obtain a consistent estimator for  $\beta$  or valid standard errors for  $\hat{\beta}$
- Efficiency gains are possible if the correlation model is correct

#### Issues

- Accommodates only one source of correlation: Longitudinal or cluster
- GEE requires that any missing data are missing completely at random
- Issues arise with time-dependent exposures and covariance weighting

## Strategies for analysis of longitudinal data

- Derived variable: Collapse the longitudinal series for each subject into a summary statistic, such as a difference (a.k.a. "change score") or regression coefficient, and use methods for independent data
  - ▶ Example: birth weight of 2nd child birth weight of 1st child
  - ▶ Might be adequate for two time points and no missing data
- Repeated measures: Include all data in a regression model for the mean response and account for longitudinal and/or cluster correlation
  - ► **Generalized estimating equations** (GEE): A marginal model for the mean response and a model for longitudinal or cluster correlation

$$g(\mathsf{E}[Y_{ij} \mid x_{ij}]) = x_{ij}\beta$$
 and  $\mathsf{Corr}[Y_{ij}, Y_{ij'}] = \rho(\alpha)$ 

► Generalized linear mixed-effects models (GLMM)

## Mixed-effects models (Laird and Ware, 1982)

- \* Contrast outcomes both within and between individuals
  - Assume that each subject has a regression model characterized by subject-specific parameters: a combination of fixed-effects parameters common to all individuals in the population and random-effects parameters unique to each individual subject
  - Although covariates allow for differences across subjects, typically cannot measure all factors that give rise to subject-specific variation
  - Subject-specific random effects induce a correlation structure

## Set-up

For subject *i* the mixed-effects model is characterized by

$$Y_i = (Y_{i1}, Y_{i2}, \dots, Y_{im_i})^{\mathsf{T}}$$
 $\beta^{\star} = (\beta_1^{\star}, \beta_2^{\star}, \dots, \beta_p^{\star})^{\mathsf{T}}$  Fixed effects
 $x_{ij} = (x_{ij1}, x_{ij2}, \dots, x_{ijp})$ 
 $X_i = (x_{i1}, x_{i2}, \dots, x_{im_i})^{\mathsf{T}}$  Design matrix for fixed effects
 $\gamma_i = (\gamma_{1i}, \gamma_{2i}, \dots, \gamma_{qi})^{\mathsf{T}}$  Random effects
 $z_{ij} = (z_{ij1}, z_{ij2}, \dots, z_{ijq})$ 
 $Z_i = (z_{i1}, z_{i2}, \dots, z_{im_i})^{\mathsf{T}}$  Design matrix for random effects
for  $i = 1, \dots, n$ ;  $j = 1, \dots, m_i$ ; and  $k = 1, \dots, p$  with  $q < p$ 

#### Linear mixed-effects model

Consider a linear mixed-effects model for a continuous outcome  $Y_{ij}$ 

Stage 1: Model for response given random effects

$$Y_{ij} = x_{ij}\beta + z_{ij}\gamma_i + \epsilon_{ij}$$

#### with

- x<sub>ii</sub> is a vector a covariates
- $ightharpoonup z_{ij}$  is a subset of  $x_{ij}$
- $\blacktriangleright$   $\beta$  is a vector of fixed-effects parameters
- $\triangleright \gamma_i$  is a vector of random-effects parameters
- $ightharpoonup \epsilon_{ii}$  is observation-specific measurement error
- Stage 2: Model for random effects

$$\gamma_i \sim N(0,G)$$
 $\epsilon_{ij} \sim N(0,\sigma^2)$ 

with  $\gamma_i$  and  $\epsilon_{ii}$  are assumed to be independent

#### Choices for random effects

Consider the linear mixed-effects models that include

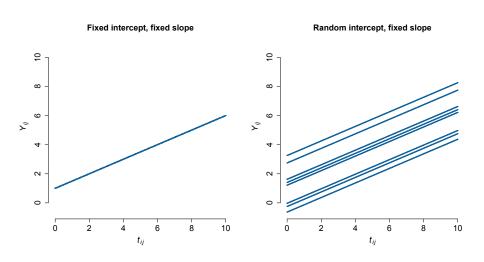

Random intercepts

$$Y_{ij} = \beta_0 + \beta_1 t_{ij} + \gamma_{0i} + \epsilon_{ij}$$
  
=  $(\beta_0 + \gamma_{0i}) + \beta_1 t_{ij} + \epsilon_{ij}$ 

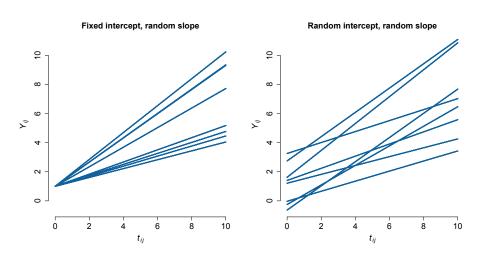

Random intercepts and slopes

$$Y_{ij} = \beta_0 + \beta_1 t_{ij} + \gamma_{0i} + \gamma_{1i} t_{ij} + \epsilon_{ij}$$
  
=  $(\beta_0 + \gamma_{0i}) + (\beta_1 + \gamma_{1i}) t_{ij} + \epsilon_{ij}$ 

## Choices for random effects

### Choices for random effects

### Choices for random effects: G

G quantifies random variation in trajectories across subjects

$$G = \left[ \begin{array}{cc} G_{11} & G_{12} \\ G_{21} & G_{22} \end{array} \right]$$

- $\sqrt{G_{11}}$  is the typical deviation in the **level** of the response
- $\sqrt{G_{22}}$  is the typical deviation in the **change** in the response
- G<sub>12</sub> is the covariance between subject-specific intercepts and slopes
  - $G_{12} = 0$  indicates subject-specific intercepts and slopes are uncorrelated
  - $G_{12} > 0$  indicates subjects with **high level** have **high rate** of change
  - $G_{12} < 0$  indicates subjects with **high level** have **low rate** of change

$$(G_{12} = G_{21})$$

### Generalized linear mixed-effects models

#### A GLMM is defined by random and systematic components

• Random: Conditional on  $\gamma_i$  the outcomes  $Y_i = (Y_{i1}, \dots, Y_{im_i})^T$  are mutually independent and have an exponential family density

$$f(Y_{ij} \mid \beta^{\star}, \gamma_i, \phi) = \exp\{[Y_{ij}\theta_{ij} - \psi(\theta_{ij})]/\phi + c(Y_{ij}, \phi)\}$$

for  $i=1,\ldots,n$  and  $j=1,\ldots,m_i$  with a scale parameter  $\phi>0$  and  $\theta_{ij}\equiv\theta_{ij}(\beta^\star,\,\gamma_i)$ 

#### Generalized linear mixed-effects models

#### A GLMM is defined by random and systematic components

• Systematic:  $\mu_{ij}^{\star}$  is modeled via a linear predictor containing fixed regression parameters  $\beta^{\star}$  common to all individuals in the population and subject-specific random effects  $\gamma_i$  with a known link function  $g(\cdot)$ 

$$g(\mu_{ij}^{\star}) = x_{ij}\beta^{\star} + z_{ij}\gamma_{i} \Leftrightarrow \mu_{ij}^{\star} = g^{-1}(x_{ij}\beta^{\star} + z_{ij}\gamma_{i})$$

where the random effects  $\gamma_i$  are mutually independent with a common underlying multivariate distribution, typically assumed to be

$$\gamma_i \sim N_q(0, G)$$

so that G quantifies random variation across subjects

## Likelihood-based estimation of $\beta$

#### Requires specification of a complete probability distribution for the data

 Likelihood-based methods are designed for fixed effects, so integrate over the assumed distribution for the random effects

$$\mathcal{L}_{Y}(\beta, \sigma, G) = \prod_{i=1}^{n} \int f_{Y|\gamma}(Y_{i} \mid \gamma_{i}, \beta, \sigma) \times f_{\gamma}(\gamma_{i} \mid G) d\gamma_{i}$$

where  $f_{\gamma}$  is typically the density function of a Normal random variable

- For linear models the required integration is straightforward because  $Y_i$  and  $\gamma_i$  are both normally distributed (easy to program)
- For non-linear models the integration is difficult and requires either approximation or numerical techniques (hard to program)

### Likelihood-based estimation of $\beta$

Two likelihood-based approaches to estimation using a GLMM

- 1. **Conditional likelihood**: Treat the random effects as if they were fixed parameters and **eliminate** them by conditioning on their sufficient statistics; does not require a specified distribution for  $\gamma_i$ 
  - xtreg and xtlogit with fe option in Stata
- 2. **Maximum likelihood**: Treat the random effects as unobserved nuisance variables and **integrate** over their assumed distribution to obtain the marginal likelihood for  $\beta$ ; typically assume  $\gamma_i \sim N(0, G)$ 
  - xtreg and xtlogit with re option in Stata
  - mixed and melogit in Stata
  - ▶ lmer and glmer in R package lme4

### 'Fixed effects' versus 'random effects'

'Fixed-effects' approach provided by conditional likelihood estimation

- Comparisons are made within individuals who act as their own control and differences are averaged across all individuals in the sample
- Could eliminate potentially large sources of bias by controlling for all stable characteristics of the individuals under study (+)
- Variation across subjects is ignored, which could provide standard error estimates that are too big; conservative inference (-)
- Although controlled for by conditioning, cannot estimate coefficients for covariates that have no within-subject variation (-/+)

### 'Fixed effects' versus 'random effects'

'Random-effects' approach provided by maximum likelihood estimation

- Comparisons are based on within- and between-subject contrasts
- Requires a specified distribution for subject-specific effects; correct specification is required for valid likelihood-based inference (-/+)
- Do not control for unmeasured characteristics because random effects are almost always assumed to be uncorrelated with covariates (-)
- Can estimate effects of within- and between-subject covariates (+)

### Assumptions

#### Valid inference from a linear mixed-effects model relies on

- **Mean model**: As with any regression model for an average outcome, need to correctly specify the functional form of  $x_{ij}\beta$  (here also  $z_{ij}\gamma_i$ )
  - Included important covariates in the model
  - Correctly specified any transformations or interactions
- Covariance model: Correct covariance model (random-effects specification) is required for correct standard error estimates for  $\hat{\beta}$
- **Normality**: Normality of  $\epsilon_{ij}$  and  $\gamma_i$  is required for normal likelihood function to be the correct likelihood function for  $Y_{ij}$
- n sufficiently large for asymptotic inference to be valid
- ★ These assumptions must be verified to evaluate any fitted model

## Motivating example

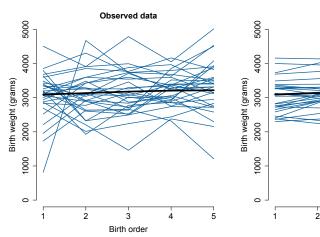

Interested in the association between birth order and birth weight

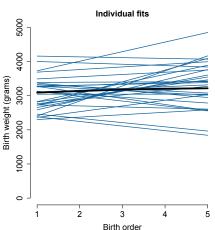

$$E[Y_{ij} \mid x_{ij}, \gamma_i] = \beta_0 + \beta_1 x_{ij1} + \beta_2 x_{ij2} + \gamma_{0i}$$
  
or  $\beta_0 + \beta_1 x_{ij1} + \beta_2 x_{ij2} + \gamma_{0i} + \gamma_{1i} x_{ij1}$ 

for  $i = 1, \dots, 200$  and  $j = 1, \dots, 5$  with

- Yii: Infant birth weight (continuous)
- $x_{ij1}$ : Infant birth order
- x<sub>ij2</sub>: Mother's initial age

# Motivating example: Comments

- Difference in mean birth weight between two populations of infants whose birth order differs by one is 46.6 grams, 95% CI: (27.0, 66.2)
- Agrees well with GEE point estimate and confidence interval
- $\sqrt{\hat{G}_{00}} = 323$  indicates substantial variability across mothers in the initial level of infant birth weight;  $\sqrt{\hat{G}_{11}} = 49$  indicates substantial variability across mothers in the trend of birth weight over time
- **Note**: Typically can specify correlated intercepts and slopes, i.e.  $G_{01} \neq 0$ , but in this case the model would not converge
- There are options for formal statistical evaluation of two randomeffects specifications, but I generally do not recommend an inferential procedure in which a *p*-value tells you to use a simpler model
- Specification for the random effects should be guided by *a priori* scientific knowledge and exploratory data analysis

### **GLMM** summary

- A GLMM is defined by a random component describing outcomes given subject-specific effects and a systematic component describing the conditional mean given subject-specific effects
- Conditional likelihood for 'fixed effects' eliminates subject-specific effects by conditioning on their sufficient statistics
- Maximum likelihood for 'random effects' integrates over the assumed distribution of the subject-specific effects
- Interpretation of parameter estimates depends on the assumed distribution for the outcome given the subject-specific effects and the specified structure for subject-specific effects

#### Issues

- GLMM requires that any missing data are missing at random
- Issues arise with time-dependent exposures and covariance weighting

### Strategies for analysis of longitudinal data

- **Derived variable**: Collapse the longitudinal series for each subject into a summary statistic, such as a difference (a.k.a. "change score") or regression coefficient, and use methods for independent data
  - ► Example: birth weight of 2nd child birth weight of 1st child
  - ▶ Might be adequate for two time points and no missing data
- Repeated measures: Include all data in a regression model for the mean response and account for longitudinal and/or cluster correlation
  - ► **Generalized estimating equations** (GEE): A marginal model for the mean response and a model for longitudinal or cluster correlation

$$g(\mathsf{E}[Y_{ij} \mid x_{ij}]) = x_{ij}\beta$$
 and  $\mathsf{Corr}[Y_{ij}, Y_{ij'}] = \rho(\alpha)$ 

► Generalized linear mixed-effects models (GLMM): A conditional model for the mean response given subject-specific random effects, which induce a (possibly hierarchical) correlation structure

$$g(E[Y_{ij} \mid x_{ij}, \gamma_i]) = x_{ij}\beta^* + z_{ij}\gamma_i$$

#### Overview

Review: Longitudinal data analysis

Case study: Longitudinal depression scores

Case study: Indonesian Children's Health Study

Case study: Carpal tunnel syndrome

Summary and resources

# Motivation and design

- Gregoire et al. (1996) published the results of an efficacy study on estrogen patches in treating postnatal depression
- 61 women with major depression, which began within 3 months of childbirth and persisted for up to 18 months postnatally, participated in a double-blind, placebo-controlled study
- Women were randomly assigned to active treatment (n = 34) or placebo (n = 27)
- Participants attended clinics monthly and at each visit self-ratings of depressive symptoms on the Edinburgh postnatal depression scale (EPDS) were measured
- EPDS is a standardized, validated, self-rating scale consisting of 10 items, each rated on a 4-point scale of 0–3
- **Goal**: Investigate the antidepressant efficacy of treatment with estrogen over time

#### Data

- Depression scores are assessed across m=7 months for the n=61 subjects in the study
- Depression scores for visit j are the longitudinal components measured on subject i

	+								
	subj	group	dep0	dep1	dep2	dep3	dep4	dep5	dep6

10.	10	placebo	25	9	12	15	12	13	20

- "Wide" form: A row for each subject
- Note that there are some missing data due to drop-out

### Exploratory analyses

- 1. Summarize the depression scores by visit and treatment group
- 2. Examine within-person correlations among depression scores, graphically and numerically
- 3. Graph depression scores over time, by treatment group; include a lowess line (smoother) for each group to summarize trends
- 4. Plot individual trajectories by treatment group

### Regression analyses

- 5. Consider collapsing the longitudinal series for each subject into a summary statistic between the baseline and sixth depression scores. Use methods for independent data to evaluate the association between change in depression scores and estrogen treatment
- 6. Reshape the data into long form and evaluate longitudinal associations between depression scores and treatment using GEE
  - Use visit as a linear variable
  - Use visit as a categorical variable
  - ▶ Evaluate whether the treatment effect varies over time

### Reshape the data

#### Recall what the data look like in wide form

• Note: There are fewer observations observed over time

### Correlation

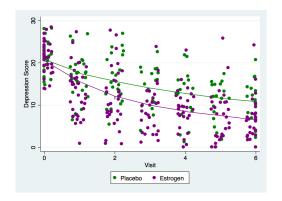

. graph matrix dep0 dep1 dep2 dep3 dep4 dep5 dep6, half

- All correlations are positive
- Strong correlation between adjacent visits

### Depression scores over time

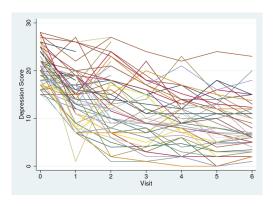

- . separate dep, by(group)
- graph twoway (scatter dep0 visit, jitter(10) mcolor(green))
   (scatter dep1 visit, jitter(10) mcolor(purple)) ///
   (lowess dep0 visit, lcolor(green)) (lowess dep1 visit, lcolor(purple))

• For each treatment arm, mean depression scores decrease over time

### Individual trajectories

. xtline dep, i(subj) t(visit) overlay legend(off)
 xlab(0(1)6) xtitle("Visit") ytitle("Depression Score")

- Reveals the complexity of individual trajectories
- Note that several patients drop out after the second visit

### Simple difference

- . gen diff=dep6-dep0
- . ttest diff, by(group) unequal

#### Two-sample t test with unequal variances

<b>.</b>		·					
Group	Obs	Mean	Std. Err.	Std. Dev.	[95% Conf.	Interval]	
placebo estrogen	17   28	-9.633529 -14.71143	1.321784 .8682517	5.449855 4.594356	-12.43559 -16.49293	-6.831472 -12.92992	
combined	l 45	-12.79311	.8158414	5.47283	-14.43733	-11.14889	
diff	Ì	5.077899	1.581447		1.845991	8.309808	
diff = mean(placebo) - mean(estrogen) t = 3.2109 Ho: diff = 0 Satterthwaite's degrees of freedom = 29.5287							
Ha: diff < 0 Ha: diff != 0 Ha: diff > $Pr(T < t) = 0.9984$ $Pr( T  >  t ) = 0.0032$ $Pr(T > t) = 0$							

- Clear decreases over time; larger decreases among estrogen group
- Limited to those with complete measurement series

### **GEE**

- A special feature of longitudinal data is that the m=7 observations that are nested within the n=61 subjects are ordered in time
- We can consider marginal models to model the within-subject dependence by allowing us to specify the covariance structure across the nested observations
- Parameters describing the covariance must be estimated along with typical regression coefficients
- A variety of options are available to describe the covariance
- Some covariance patterns require more information (i.e., require more parameters to be estimated than others)
- Recall, we identify the data as a "panel" data set using the xtset command in Stata

### Assumptions

To account for the repeated measures we can use generalized estimating equations which include all of the data over the time points in a marginal model for the mean response and account for the longitudinal correlation

$$g(\mathsf{E}[Y_{ij} \mid x_{ij}]) = x_{ij}\beta$$
 and  $\mathsf{Corr}[Y_{ij}, Y_{ij'}] = \rho(\alpha)$ 

#### Assumptions

- Observations are independent across subjects
- Observations could be correlated within subjects
- Missing data are missing completely at random

### Model

 Using the GEE framework, we consider the "cross-sectional" model where we are interested in the average treatment effect over time

$$\mathsf{E}[Y_{ij} \mid x_{ij}] = \beta_0 + \beta_1 x_{ij1} + \beta_2 x_{ij2}$$

#### with

- ► *Y<sub>ij</sub>*: continuous depression score (dep)
- x<sub>ij1</sub>: continuous variable for visit (visit)
- $x_{ij2}$ : binary treatment group with 1=estrogen, 0=placebo (group)
- For the continuous outcome, we use an identity link, link(iden), in the Gaussian family, fam(gaus); these are the default
- In Stata, xtgee allows us to specify various working covariance structures through the corr option; the command estat wcorr allows us to view the working correlation matrix

#### Correlation structures

- Independence: Observations are assumed to be independent
  - ▶ For correlation between any two observations on the same subject we assume that  $Corr[Y_{ij}, Y_{ij'}] = 0$
  - It is unlikely that for any subject, depression scores are independent from one visit to the next
- **Exchangeable**: Correlations are assumed to be constant between any two observations on the same subject;  $Corr[Y_{ij}, Y_{ij'}] = \alpha$
- AR(1): Correlation is assumed to decay as a function of time or distance between observations;  $Corr[Y_{ij}, Y_{ij'}] = \alpha^{|j-j'|}$ 
  - Likely to be appropriate in cases where there are a reasonable number of repeated measurements over time
  - ► Given that our data are measured over time, using the AR(1) correlation might help increase efficiency of SE estimation
- **Unstructured**: No relationship is imposed on dependence over time or within subjects;  $Corr[Y_{ij}, Y_{ij'}] = \alpha_{jj'}$
- \* Robust variance estimator protects against incorrect choice

### **GEE-independence**

## Modeling time

- Valid inference from GEE requires that the mean model is correct
- We have two covariates: treatment group is binary, time is ?
- Instead of a continuous variable (or, grouped linear term) for time, consider a categorical variable

$$E[Y_{ij} \mid x_{ij}] = \beta_0 + \beta_2 x_{ij2} + \beta_3 x_{ij3} + \beta_4 x_{ij4}$$
$$+ \beta_5 x_{ij5} + \beta_6 x_{ij6} + \beta_7 x_{ij7} + \beta_8 x_{ij8}$$

with, in addition to  $x_{ij2}$  representing the treatment variable (group)

- $\triangleright$   $x_{ij3}$ : dummy variable for visit 1 compared to visit 0
- $x_{ij4}$ : dummy variable for visit 2 compared to visit 0

► x<sub>ii8</sub>: dummy variable for visit 6 compared to visit 0

# GEE-AR(1), categorical time

estrogen	-2.593467	.9610867	-2.70	0.007	-4.477163	709772
_cons	22.48587	.7687195	29.25	0.000	20.9792	23.99253

### Modeling time

- Strong evidence that depression scores vary over time
  - . testparm i.visit

```
(1) 1.visit = 0
(2) 2.visit = 0
(3) 3.visit = 0
(4) 4.visit = 0
(5) 5.visit = 0
(6) 6.visit = 0
```

```
chi2(6) = 287.46
Prob > chi2 = 0.0000
```

- In the model with continuous visit, the difference in mean score between groups was -2.53 and it was highly significant (p = 0.008)
- When considering categorical visit, the difference in mean score between groups was -2.59 and it was highly significant (p = 0.007)
- Noting that the estimated treatment effect is the same in both models, we opt for the parsimony of the model with continuous visit

### Model with interaction

Consider a model that allows the treatment effect to depend on time

The model of interest becomes

$$E[Y_{ij} \mid x_{ij}] = \beta_0 + \beta_1 x_{ij1} + \beta_2 x_{ij2} + \beta_3 (x_{ij1} \times x_{ij2})$$

where  $Y_{ij}$  is the continuous depression score,  $x_{ij1}$  is a continuous variable for visit, and  $x_{ij2}$  is the treatment variable

- · Model includes their main effects and the interaction term
- For subjects in the placebo group  $(x_{ij2} = 0)$ , the model is

$$\mathsf{E}[Y_{ij} \mid x_{ij}] = \beta_0 + \beta_1 x_{ij1}$$

• For subjects in the estrogen group  $(x_{ij2} = 1)$ , the model is

$$E[Y_{ij} | x_{ij}] = (\beta_0 + \beta_2) + (\beta_1 + \beta_3)x_{ij1}$$

• Now we can compare whether the mean change in depression score over time differs between treatment groups ("longitudinal" model)

group   estrogen   	668246	.9514551	-0.70	0.482	-2.533064	1.196572
group#c.visit   estrogen	7209406	.250909	-2.87	0.004	-1.212713	2291681
_cons	19.9757	.7700831	25.94	0.000	18.46636	21.48503

### Interpretation

 Estimate the change over time for the estrogen group by adding the coefficients for the visit variable and the interaction term

```
. lincom visit + 1.group#c.visit

(1) visit + 1.group#c.visit = 0

dep | Coef. Std. Err. z P>|z| [95% Conf. Interval]

(1) | -2.366076 .1471451 -16.08 0.000 -2.654475 -2.077677
```

- For a population of women on placebo treatment, mean depression score decreases by approximately 1.65 points for each additional visit, 95% CI: (-2.04, -1.25)
- For a population of women on estrogen treatment, mean depression score decreases by approximately 2.37 points for each additional visit, 95% CI: (-2.65, -2.08)
- Strong evidence that these associations are different (p = 0.004)

### Summary

- GEE is specified by a mean model and a correlation model
  - ► We created a linear regression model for the average depression score and modeled the longitudinal correlation using an AR(1) structure
- GEE requires that the mean model is correctly specified
  - We explored different options for modeling temporal trends
- GEE provides valid estimates and standard errors for the regression parameters even under misspecification of the correlation structure, but efficiency gains are possible if the correlation model is correct
  - ▶ We chose AR(1) with the robust option
- Model with a group-by-time interaction term facilitated estimation of changes over time within groups and between-group comparisons in temporal trends
  - ► Contrasted this with a cross-sectional model that compared the mean depression score between groups over all times

#### Overview

Review: Longitudinal data analysis

Case study: Longitudinal depression scores

Case study: Indonesian Children's Health Study

Case study: Carpal tunnel syndrome

Summary and resources

# Indonesian Children's Health Study (ICHS)

- Determine the effects of vitamin A deficiency in preschool children
- n = 275 children examined for respiratory infection at up to 6 visits
- Xerophthalmia is an ocular manifestation of vitamin A deficiency
- Goal: Evaluate association between vitamin A deficiency and risk of respiratory infection

		Age (years)							
${\sf Xerophthalmia}$	Infection	0	1	2	3	4	5	6	7
No	No	77	229	154	196	176	143	65	5
No	Yes	8	30	30	15	9	7	1	0
Yes	No	0	1	9	10	15	8	4	1
Yes	Yes	0	0	4	3	0	0	0	0

Multiple records per person, with age in months, centered at 36 months, and time indicating visit number

### Exploratory analyses

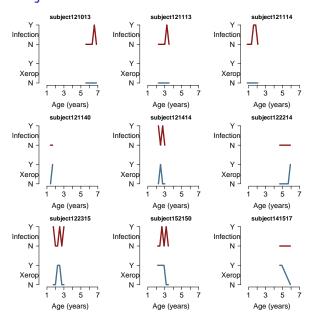

- 1. Plot vitamin A deficiency and infection status, by age, for a sample of individuals
- 2. Plot percent with respiratory infection versus age, by presence or absence of vitamin A deficiency
- 3. Explore correlation structure by visit number, and calculate percent with respiratory infection at each visit

## Regression analyses

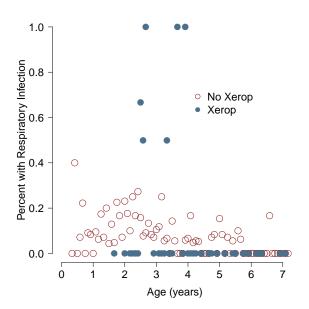

- 4. Evaluate the association between respiratory infection and vitamin A deficiency using an ordinary logistic regression model
- 5. Use GEE to estimate the population-averaged odds ratio for respiratory infection, comparing those with vitamin A deficiency to those without, given equivalent values of other covariates. Explore multiple specifications of working correlation
- 6. Use GLMM to estimate the conditional odds ratio for respiratory infection, comparing a typical individual with vitamin A deficiency to a typical individual without, given equivalent values of other covariates. Estimate the variability in the probability of respiratory infection across individuals

Answers

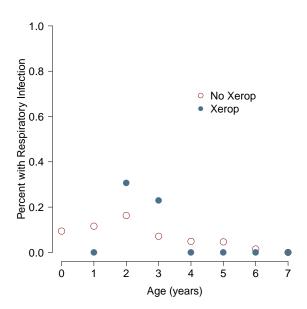

### Individual trajectories

## Monthly averages

## Yearly averages

### Logistic regression model

- $\exp \beta_1 = 2.08$
- 95% CI: (0.88, 4.88)
- Does not take into account within-person correlation

#### **GEE** motivation

Do vitamin A deficient children have an increased risk of infection?

$$\begin{array}{rcl} \mu_{ij} & = & \mathsf{E}[Y_{ij} \mid x_{ij}] \\ & = & \mathsf{P}[Y_{ij} = 1 \mid x_{ij}] \\ \\ \mathsf{logit}\,\mu_{ij} & = & \mathsf{log}\,\frac{\mu_{ij}}{1 - \mu_{ij}} \\ & = & \beta_0 + \beta_1\,\mathsf{Xerophthalmia}_{ij} + \cdots \\ \\ & \approx & \mathsf{log}\,\frac{\mathsf{P}[Y_{ij} = 1 \mid x_{ij}]}{\mathsf{P}[Y_{ij} = 0 \mid x_{ij}]} \end{array}$$

- $\exp \beta_1$  represents the ratio of the expected odds of respiratory infection among a population of vitamin A deficient children to that for a population of children replete with vitamin A of the same age, gender, ...
- $\exp \beta_1$  is therefore a **population-averaged** parameter
- Respiratory infection is rare so odds ratio approximates relative risk

#### Correlations

• Use visit time (not age) to obtain a correlation matrix with n=146–229 observations per cell

	Time 1	Time 2	Time 3	Time 4	Time 5	Time 6
Time 1	1					
Time 2	0.06	1				
Time 3	0.07	0.11	1			
Time 4	0.24	-0.03	0.06	1		
Time 5	0.07	0.26	0.19	-0.01	1	
Time 6	0.05	0.12	-0.07	0.06	0.10	1
	13 %	5 %	7 %	4 %	15 %	9 %

#### Covariance structure

For a binary outcome, variance depends on mean

$$\mathsf{Var}[Y_{ij}] = \mathsf{E}[Y_{ij}](1 - \mathsf{E}[Y_{ij}])$$

- Correlation also depends (in a somewhat complicated way) on pairwise means
- NB
  - With respect to age, data are neither balanced nor complete
  - ► Even if our analysis will be a function of age, examination of covariance and correlation matrices with respect to visit time is useful
  - Dependence of correlation on pairwise means motivates alternate methods that model odds ratios instead of correlations

#### Covariance structure

- Odds ratios measure the association between two binary variables
- Here, binary outcomes at two different visit times

	Time 1	Time 2	Time 3	Time 4	Time 5	Time 6
Time 1	$\infty$					
Time 2	1.93	$\infty$				
Time 3	2.10	4.62	$\infty$			
Time 4	8.60	0	2.38	$\infty$		
Time 5	1.76	11.9	4.68	0.92	$\infty$	
Time 6	1.63	3.73	0	2.18	2.14	$\infty$

#### Covariance structure

Variance model

$$\mathsf{Var}[Y_{ij} \mid x_{ij}] = \mu_{ij}(1 - \mu_{ij})$$

- Consider various specifications for the 'working' correlation structure
  - Independence
  - Exchangeable
  - Auto-regressive

**NB**: In practice, selection of a working correlation structure should be guided by a priori knowledge and/or exploratory analysis

### geepack

- geepack implements estimating equations for eta, lpha, and  $\phi$
- geeglm
  - Syntax similar to glm; returns an object similar to a glm object
  - An anova method provides multivariate Wald tests for joint hypotheses
  - ► Calls a fitter function geese to solve the estimating equations
- geese
  - Provides estimation and inference for  $\beta$ ,  $\alpha$ , and  $\phi$
  - Model objects are available within geeglm objects

```

### Mixed-effects models

Do vitamin A deficient children have an increased risk of infection?

$$\begin{array}{rcl} \mu_{ij}^{\star} & = & \mathsf{E}[Y_{ij} \mid \gamma_{0i}] \\ & = & \mathsf{P}[Y_{ij} = 1 \mid \gamma_{0i}] \end{array}$$

$$\begin{split} \log &\mathrm{it}\, \mu_{ij}^{\star} &= &\log \frac{\mu_{ij}^{\star}}{1-\mu_{ij}^{\star}} \\ &= &(\beta_{0}^{\star}+\gamma_{0i})+\beta_{1}^{\star}\,\mathrm{Xerophthalmia}_{ij}+\cdots \end{split}$$

for i = 1, ..., 275 and  $j = 1, ..., m_i$ 

- $\exp \beta_1^\star$  represents the ratio of the expected odds of respiratory infection for a typical individual with vitamin A deficiency to that for a typical individual with a sufficient amount of vitamin A of the same age, gender, . . .
- $\exp \beta_1^{\star}$  is therefore a **conditional** parameter
- Respiratory infection is rare so odds ratio approximates relative risk

#### R commands

 Use the glmer command in the lme4 library library(lme4) ?glmer m\_ri <- glmer(infection ~ (1 | id) + factor(xerop)</pre> + age + factor(gender) + hfora + cost + sint, family=binomial, data=ichs, nAGQ=7) methods(class="merMod") expit <- function(x) $\{\exp(x)/(1+\exp(x))\}$ expit(fixef(m\_ri)[1]) expit(fixef(m\_ri)[1]-1.96\*sqrt(VarCorr(m\_ri)\$id[[1]])) expit(fixef(m\_ri)[1]+1.96\*sqrt(VarCorr(m\_ri)\$id[[1]]))

### Random intercepts model

```
> summary(m_ri)
```

# Interpreting random effects components

- For continuous outcomes interpreting random effects is 'easy' because their standard deviation is on the scale of the outcome
- For binary outcomes the standard deviation is on the log-odds scale
- Recall for a GLMM with random intercepts

$$\gamma_{0i} \sim N(0, G_{11}) \Leftrightarrow (\beta_0^{\star} + \gamma_{0i}) \sim N(\beta_0^{\star}, G_{11})$$

- In the ICHS analysis the intercept corresponds to the log odds of respiratory infection among females, age 36 months, ..., with a sufficient amount of vitamin A
- We can use  $\hat{\beta}_0^{\star}$  and  $\hat{G}_{11}$  to form an interval to quantify variability in the probability of respiratory infection across these individuals

$$ext{expit}(\hat{eta}_0^{\star} \pm 1.96 imes \hat{G}_{11}) = rac{\exp(\hat{eta}_0^{\star} \pm 1.96 imes \hat{G}_{11})}{1 + \exp(\hat{eta}_0^{\star} \pm 1.96 imes \hat{G}_{11})},$$

which is calculated to be 0.06 (0.01, 0.28)

• **NB**: This is **not** a confidence interval for  $\beta_0^*$ 

# Conditional and marginal effects

- Parameter estimates obtained from a marginal model (as obtained via a GEE) estimate population-averaged contrasts
- Parameter estimates obtained from a conditional model (as obtained via a GLMM) estimate subject-specific contrasts
- In a linear model for a Gaussian outcome with an identity link these contrasts are equivalent; not the case with non-linear models
  - Depends on the outcome distribution
  - Depends on the specified random effects

# Conditional and marginal effects

		Fitted conditional model				
Outcome	Coefficient	Random intercept	Random intercept/slope			
Continuous	Intercept	Marginal	Marginal			
	Slope	Marginal	Marginal			
Count	Intercept	Conditional	Conditional			
	Slope	Marginal	Conditional			
Binary	Intercept	Conditional	Conditional			
	Slope	Conditional	Conditional			

<sup>★</sup> Marginal = population-averaged; conditional = subject-specific

# Summary

- Exploratory analysis with binary outcomes is not straightforward
  - ▶ Plots of raw data not always useful
  - ▶ Aggregated percents (means) can summarize mean response
  - Correlation can be examined using correlations or odds ratios
- GEE provides marginal, population-averaged contrasts
  - Ratio of the expected odds of respiratory infection among a population of vitamin A deficient children to that for a population of children replete with vitamin A of the same age, gender, ...
- GLMM provides conditional, subject-specific contrasts
  - Ratio of the expected odds of respiratory infection for a typical individual with vitamin A deficiency to that for a typical individual with a sufficient amount of vitamin A of the same age, gender, . . .
  - ▶ Random effects variance components quantify heterogeneity in effects
- Lack of significance likely due to small number of exposed cases

### Overview

Review: Longitudinal data analysis

Case study: Longitudinal depression scores

Case study: Indonesian Children's Health Study

Case study: Carpal tunnel syndrome

Summary and resources

# Carpal tunnel syndrome trial

- Jarvik et al. (2009) compared surgical versus non-surgical treatment for carpal tunnel syndrome (CTS)
- 116 participants were randomized
- Outcomes were assessed using the CTS assessment questionnaire (CTSAQ), every 3 months for 12 months
  - ▶ Primary: functional status (low values are favorable)
  - Secondary: symptom severity
- Crossover to surgery was allowed after 3 months
- Goal: Determine whether surgery improves functional status

### **Variables**

- ID: unique participant ID
- idgroup: study site
   (1 = private, 2 = UW, 3 = VA, 4 = HMC)
- age: age in years
- gender (0 = male, 1 = female)
- treatassign: randomized intervention
   (0 = non-surgery, 1 = surgery)
- surgreported#: surgery reported at visit #
   (0 = no, 1 = yes)
- ctsaqf#: CTSAQ functional status at visit #
- ullet ctsaqs#: CTSAQ symptom severity at visit #
- surgical: treated surgically during study (0 = never, 1 = 0-3 mos, 2 = 3-6 mos, 3 = 6-9 mos, 4 = 9-12 mos)

## Exploratory analyses

- 1. Plot individual trajectories in CTSAQF over time by treatment
- 2. Plot average CTSAQF over time by treatment
- 3. Summarize means, variances, and correlations over time by treatment

# Regression analyses (intention-to-treat)

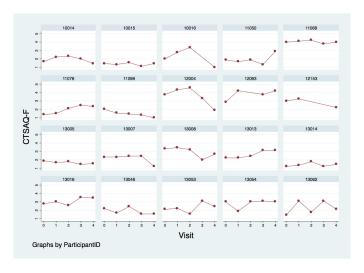

- 4. Evaluate POST, CHANGE, and ANCOVA models for each timepoint with CTSAQF as outcome
  - ▶ POST: follow-up measurement only
  - ► CHANGE: difference between follow-up and baseline measurement
  - ► ANCOVA: follow-up measurement controlling for baseline
- 5. Evaluate difference in mean CTSAQF between treatments at 12 months, adjusted for baseline CTSAQF and study site
- Using repeated measures regression models, evaluate difference in mean CTSAQF between treatments using all timepoints, adjusted for baseline CTSAQF and study site

# Bonus analyses (as treated)

- 7. Summarize actual treatment patterns by assigned treatment group
- 8. Plot average CTSAQF by visit...
  - For those who received surgery by 3 months versus those who did not
  - ▶ For those who received surgery by 9 months versus those who did not
- Use linear mixed-effects models to estimate differences in mean CTSAQF when exposure is surgery by 3 months and surgery by 9 months instead of assigned treatment group

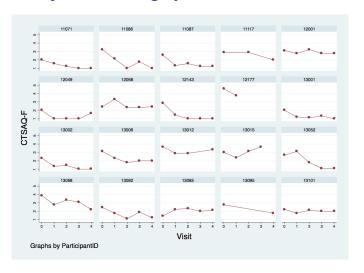

Answers

# Individual trajectories, non-surgery arm

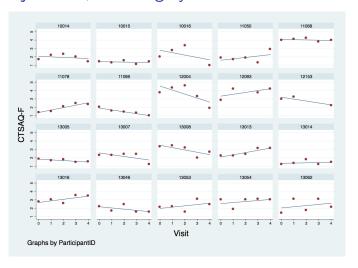

graph twoway connected ctsaqf visit if(ID<=13062 & ID!=13009 & treatassign==0),

graph twoway (scatter ctsaqf visit if treatassign==0) (line ctsaqf visit if treatassign==0)
(scatter ctsaqf visit if treatassign==1) (line ctsaqf visit if treatassign==1)

### Means and variances

- . use "cts.dta". clear
- . bysort treatassign: summarize ctsaqf0 ctsaqf1 ctsaqf2 ctsaqf3 ctsaqf4
- -> treatassign = 0

Variable	Obs	Mean	Std. Dev.	Min	Max
ctsaqf0 ctsaqf1 ctsaqf2 ctsaqf3 ctsaqf4	56   54   46	2.526164 2.428075 2.440586 2.309136 2.169948	.8197035 .9304938 .8689515 .9266844 .9620186	1 1.111111 1.111111 1 1	4.444445 4.555555 4 4.222222

-> treatassign = 1

Variable	0bs	Mean	Std. Dev.	Min	Max
ctsaqf0	57	2.418616	.81565	1	4.555555
ctsaqf1	51	2.20347	.8369104	1	4
ctsaqf2	J 50	1.911667	.8834815	1	4.111111
ctsaqf3	l 48	1.835069	.7985738	1	3.777778
ctsaqf4	1 49	1.740079	.789603	1	4.111111

- Both treatment groups improve, but surgery group improves more
- Variance is larger in non-surgery group after baseline
- Missing data exist in both treatment groups

### Correlation

-> treatassign = 0

. bysort treatassign: cor ctsaqf0 ctsaqf1 ctsaqf2 ctsaqf3 ctsaqf4

- Strong positive correlations across most measurement pairs
- Note: Only a subset of participants has measurements at all times

# Generate change variables

```

# Summary

- Small but statistically significant difference between groups, showing an improvement due to surgical treatment
- Analyses focused on average "cross-sectional" differences; could also explore differences in trends between groups
- Consistent results across analyses, even though different methods require different assumptions, particularly regarding missing data
- Reasonable people disagree about how to include baseline measurements in repeated measures regression models...
  - As a covariate (as was done here)
  - As an outcome
- Intention-to-treat estimate possibly understated due to crossovers;
   as-treated analyses are subject to possible selection biases

### Overview

Review: Longitudinal data analysis

Case study: Longitudinal depression scores

Case study: Indonesian Children's Health Study

Case study: Carpal tunnel syndrome

Summary and resources

# Big picture: GEE

- Marginal mean regression model
- Model for longitudinal correlation
- Semi-parametric model: mean + correlation
- Form an unbiased estimating function
- Estimates obtained as solution to estimating equation
- Model-based or empirical variance estimator
- Robust to correlation model mis-specification
- Large sample:  $n \ge 40$
- Testing with Wald tests
- Marginal or population-averaged inference
- Efficiency of non-independence correlation structures
- Missing completely at random (MCAR)
- Time-dependent covariates and endogeneity
- Only one source of positive or negative correlation
- R package geepack; Stata command xtgee

# Big picture: GLMM

- Conditional mean regression model
- Model for population heterogeneity
- Subject-specific random effects induce a correlation structure
- Fully parametric model based on exponential family density
- Estimates obtained from likelihood function
- Conditional (fixed effects) and maximum (random effects) likelihood
- $\bullet$  Approximation or numerical integration to integrate out  $\gamma$
- Requires correct parametric model specification
- Testing with likelihood ratio and Wald tests
- Conditional or subject-specific inference
- Induced marginal mean structure and 'attenuation'
- Missing at random (MAR)
- Time-dependent covariates and endogeneity
- Multiple sources of positive correlation
- R package lme4; Stata commands mixed, melogit

# Final summary

### Generalized estimating equations

- Provide valid estimates and standard errors for regression parameters of interest even if the correlation model is incorrectly specified (+)
- ullet Empirical variance estimator requires sufficiently large sample size (-)
- Always provide population-averaged inference regardless of the outcome distribution; ignores subject-level heterogeneity (+/-)
- Accommodate only one source of correlation (-/+)
- ullet Require that any missing data are missing completely at random (-)

# Final summary

#### Generalized linear mixed-effects models

- Provide valid estimates and standard errors for regression parameters only under stringent model assumptions that must be verified (-)
- Provide population-averaged or subject-specific inference depending on the outcome distribution and specified random effects (+/-)
- Accommodate multiple sources of correlation (+/-)
- Require that any missing data are missing at random (-/+)

### Advice

- Analysis of longitudinal data is often complex and difficult
- You now have versatile methods of analysis at your disposal
- Each of the methods you have learned has strengths and weaknesses
- Do not be afraid to apply different methods as appropriate
- Statistical modeling should be informed by exploratory analyses
- Always be mindful of the scientific question(s) of interest
