Introduction 000000	Masses and profiles	χ^2 , inertia and profiles 00000	SVD and biplot	Supplementary points	Contributions 000
Object	ive				

- Study the relationship between two (or more) categorical variables.
- Provide a picture of a contingency table.

- Microsatellites consist of short sequences (e.g. ATT) that repeat a certain number of times (e.g. ATTATTATTATT).
- A small (2-6) number of base pairs is repeated.
- Individuals vary in the number of repeats they have.
- Produces count data, with a limited number of outcomes.
- Microsatellites have many alleles.

- STRs can be coded in different ways:
 - reporting the number of repeats an individual has on each chromosome.
 - reporting the total size of the repeating sequences as the number of base pairs on each chromosome.
- Example:
 - a tri-nucleotide STR: ATT.
 - an individual has the DNA sequences (ATTATTATT,ATTATTCAA)
 - can be coded as (3/2) (repeats)
 - (9/6) (total size)
- In the statistical analysis mostly treated as categorical.

Some notation

- For the sake of illustration, we here disregard the Hispanic sample
- N the $I \times J$ contingency table. P = N/n with n = 1'N1, and thus 1'P1 = 1.
- P a matrix of probabilities (the correspondence matrix).

Row masses

$$r_i = \sum_{j=1}^{J} p_{ij}$$
 $\mathbf{r} = \mathbf{P1}$ $\mathbf{D}_r = diag(\mathbf{r})$

Column masses

$$c_j = \sum_{i=1}^{l} p_{ij}$$
 $\mathbf{c} = \mathbf{P}' \mathbf{1}$ $\mathbf{D}_c = diag(\mathbf{c})$

- A profile is a vector of non-negative elements that sum 1.
- The contingency table can be converted into a matrix of profiles.

- Row (column) profiles are obtained by summing the elements of a row (column) in **P** and dividing by the total.
- $\mathbf{R} = \mathbf{D}_r^{-1}\mathbf{P}$ row profiles $\mathbf{C} = \mathbf{D}_c^{-1}\mathbf{P}'$ column profiles
- Row and column masses turn out be weighted averages of the profiles

$$\mathbf{r}'\mathbf{D}_r^{-1}\mathbf{P} = \mathbf{1}'\mathbf{P} = \mathbf{c}'$$
 $\mathbf{c}'\mathbf{D}_c^{-1}\mathbf{P}' = \mathbf{1}'\mathbf{P}' = \mathbf{r}'$

- The profile matrix for the data under consideration has rank 2.
- In this case, the profiles can be represented in a ternary plot.

- The column rank of the matrix of row profiles is at most J-1
- The row rank of the matrix of column profiles is at most I-1
- "The" rank of the CA solution is min(I-1, J-1)

Profiles	and v^2 st	atistic			
Introduction 0000000	Masses and profiles	χ^2 , inertia and profiles 0000	SVD and biplot 00000	Supplementary points	Contributions

$$\chi^{2} = \sum_{i,j} \frac{(n_{ij} - e_{ij})^{2}}{e_{ij}} = \sum_{i,j} \frac{(n_{ij} - n_{i}c_{j})^{2}}{n_{i}c_{j}} = n \sum_{i,j} \frac{(p_{ij} - r_{i}c_{j})^{2}}{r_{i}c_{j}}$$

$$\frac{\chi^2}{n} = \sum_{i,j} \frac{(p_{ij} - r_i c_j)^2}{r_i c_j} = \sum_{i,j} r_i^2 \frac{(\frac{p_{ij}}{r_i} - c_j)^2}{r_i c_j} = \sum_{i,j} r_i \frac{(\frac{p_{ij}}{r_i} - c_j)^2}{c_j} = \sum_i r_i \sum_j \frac{(\frac{p_{ij}}{r_i} - c_j)^2}{c_j}$$

Likewise, for column profiles

 Λ

$$\frac{\chi^2}{n} = \sum_j c_j \sum_i \frac{(\frac{p_{ij}}{c_j} - r_i)^2}{r_i}$$

• The quantity $\frac{\chi^2}{n}$ is known as the total inertia of the contingency table.

- Note that ∑_j (^p_{ij}/_{r_i} − c_j)² is squared Euclidean distance between profile i and average row profile
- Note that $\sum_{j} \frac{1}{c_j} (\frac{p_{ij}}{r_i} c_j)^2$ is weighted squared Euclidean distance between profile *i* and average row profile (called χ^2 distance)
- Inertia is a weighted average of weigthed squared Euclidean distances.
- Inertia is a measure of spread of the profiles w.r.t. their average.

Introduction 0000000	Masses and profiles	χ^2 , inertia and profiles 00000	SVD and biplot	Supplementary points	Contributions 000

The geometrical interpretation of Inertia

Inertia = 0.001 Inertia = 0.017 В С A В С A 22 3 4 4¹2 35 **4** 2 Inertia = 0.184 Inertia = 1.145 В С В A A C 3 4 5 3

Introduction 0000000	Masses and profiles	χ^2 , inertia and profiles 00000	SVD and biplot 00000	Supplementary points	Contributions
Limitin	g situations	S			

- Perfect independence: minimal inertia = $0, \chi^2 = 0$.
- Perfect association: maximal inertia = min(I 1, J 1).

0000000		χ , mertia and profiles	00	000
Larger	tables			

- The profiles of genotypes over three populations data can be represented exactly in two-dimensional space
- Profiles of $I \times J$ contingency table can be represented exactly in min(I 1, J 1) dimensional space.
- We search for an approximation of the profiles in one, two or at most three dimensions.
- The approximation is obtained by a (weighted) singular value decomposition.
- The criterion is to miminize errors in the approximation of the profiles, which is equivalent to maximizing the inertia of the profiles in a k dimensional subspace.
- The optimal solution can be obtained in several ways, here we use the svd of the standardized residuals of the contingency table.

•
$$\mathbf{E} = \mathbf{P} - \mathbf{rc'}$$
 deviations from independence
• $\mathbf{D}_r^{-1/2} \mathbf{E} \mathbf{D}_c^{-1/2} = \mathbf{D}_r^{-1/2} (\mathbf{P} - \mathbf{rc'}) \mathbf{D}_c^{-1/2}$ "standardized residuals"

$$\mathbf{D}_r^{-1/2} (\mathbf{P} - \mathbf{rc}') \mathbf{D}_c^{-1/2} = \mathbf{U} \mathbf{D} \mathbf{V}'$$

Standard coordinates

$$\mathbf{F}_s = \mathbf{D}_r^{-1/2}\mathbf{U}$$
 $\mathbf{G}_s = \mathbf{D}_c^{-1/2}\mathbf{V}$

Principal coordinates

$$\mathbf{F}_{p} = \mathbf{D}_{r}^{-1/2}\mathbf{U}\mathbf{D} = \mathbf{F}_{s}\mathbf{D}$$
 $\mathbf{G}_{p} = \mathbf{D}_{c}^{-1/2}\mathbf{V}\mathbf{D} = \mathbf{G}_{s}\mathbf{D}$

Graphical output of Correspondence analysis

- Joint plot of the rows of \mathbf{F}_s and \mathbf{G}_p (biplot of scaled row profiles)
- Joint plot of the rows of \mathbf{F}_{p} and \mathbf{G}_{s} (biplot of scaled column profiles) ۰
- Joint plot of the rows of $\mathbf{D}_r^{-1/2}\mathbf{U}\mathbf{D}_2^{\frac{1}{2}}$ and $\mathbf{D}_c^{-1/2}\mathbf{V}\mathbf{D}_2^{\frac{1}{2}}$ ("symmetric" biplot) ۲
- Joint plot of the rows of \mathbf{F}_p and \mathbf{G}_p (not a biplot) ۰
- note that $\mathbf{F}_{s}\mathbf{G}_{p}' = \mathbf{D}_{r}^{-1/2}\mathbf{U}\mathbf{D}\mathbf{V}'\mathbf{D}_{c}^{-1/2} = (\mathbf{D}_{r}^{-1}\mathbf{P} \mathbf{1}\mathbf{c}')\mathbf{D}_{c}^{-1}$
- and that $\mathbf{G}_{s}\mathbf{F}_{p}{}' = \mathbf{D}_{c}{}^{-1/2}\mathbf{V}\mathbf{D}\mathbf{U}'\mathbf{D}_{r}{}^{-1/2} = (\mathbf{D}_{c}{}^{-1}\mathbf{P}' \mathbf{1}\mathbf{r}')\mathbf{D}_{r}{}^{-1}$
- for convenience, the biplot vectors can be scaled, by the premultiplication of G_s by $\mathbf{D}_{c}^{1/2}$, or of \mathbf{F}_{s} by $\mathbf{D}_{r}^{1/2}$ (the "contribution" biplot). This often pulls in outlying categories with small weight.

	1	2
Eigenvalue	0.458	0.127
Proportion	0.783	0.217
Cumulative	0.783	1.000

Note that

$$\frac{\chi^2}{n} = \frac{467.952}{800} = 0.585 = 0.458 + 0.127$$

From previous results

- $\mathbf{F}_p = \mathbf{D}_r^{-1} \mathbf{P} \mathbf{G}_s$
- $\mathbf{G}_p = \mathbf{D}_c^{-1} \mathbf{P}' \mathbf{F}_s$
- Principal coordinates of the rows are weighted averages of standard coordinates of the columns
- Useful for calculating coordinates of supplementary points

- Supplementary points or inactive points are rows (columns) of the data matrix, usually collected under different conditions, that do not intervene in the computation of the solution.
- However, their representation in a biplot, posterior to the analysis, can be helpful for interpretation.
- Supplementary points can be situated in CA biplots by expressing them as profiles and using the transition relationships.

- In PCA we have seen that the total variance of data matrix can be decomposed into contributions made by dimensions (principal components), by variables, and finally by individual observations.
- In CA, a similar decomposition is possible, where the total inertia of a contingency table can be decomposed into contributions made by dimensions (principal axis), by the rows of the table, the columns of the table, and finally, the individual cells of a table.
- Such a decomposition is useful for spotting influential points in the analysis.

we had

$$\frac{\chi^2}{n} = \sum_i r_i \sum_j \frac{(\frac{p_{ij}}{r_i} - c_j)^2}{c_j} = \sum_j c_j \sum_i \frac{(\frac{p_{ij}}{c_j} - r_i)^2}{r_i}$$

- each row (and column) make a contribution to the total inertia, these are called row and column inertias.
- note that

$$\frac{\chi^2}{n} = \sum_{i,j} \frac{(p_{ij} - r_i c_j)^2}{r_i c_j} = tr(\mathbf{D}_r^{-1}(\mathbf{P} - \mathbf{rc}')\mathbf{D}_c^{-1}(\mathbf{P} - \mathbf{rc})') = tr(\mathbf{D}^2)$$

- squared singular values (eigenvalues) are called principal inertias and constitute the contribution of each dimension in the solution to the total
- the inertias of each row (column) can be decomposed into contributions made by the principal axis. This allows one to judge how much of the inertia of each row (column) is accounted for by each axis, and to compute goodness-of-fit statistics for each point.
