## Contents

(1) Error rate and cross validation
(2) Multi-group LDA

## Error rates and Confusion matrix

- It is of interest to evaluate the performance of a classification rule.
- There are several criteria to do so.
- Actual error rate (AER, density dependent)

$$
\mathrm{AER}=p_{1} \int_{\hat{R}_{2}} f_{1}(\mathbf{x}) d \mathbf{x}+p_{2} \int_{\hat{R}_{1}} f_{2}(\mathbf{x}) d \mathbf{x}
$$

- Apparent error rate (APER, not density dependent) based on the confusion matrix

|  |  | Predicted class |  |
| :---: | :---: | :---: | :---: |
|  |  | $\pi_{1}$ | $\pi_{2}$ |
| True | $\pi_{1}$ | $n_{11}$ | $n_{12}$ |
| Class | $\pi_{2}$ | $n_{21}$ | $n_{22}$ |

- APER obtained as

$$
\mathrm{APER}=\frac{n_{12}+n_{21}}{n_{1}+n_{2}}
$$

- APER underestimates the AER.

## Jackknife or hold-one-out

## Procedure:

- Take the data from group $\pi_{1}$. Omit the $i$ th observation, build the classifier with $n_{1}-1+n_{2}$ observations.
- Classify the ith observation using the classifier.
- Repeat for all observations in $\pi_{1}$.
- Calculate $n_{1 M}^{H}$, the number of observations that were held out and misclassified.
- Do the same for group $\pi_{2}$ and calculate $n_{2 M}^{H}$.
- Obtain an estimate of the expected actual error rate

$$
E(\mathrm{AER})=\frac{n_{1 M}^{H}+n_{2 M}^{H}}{n_{1}+n_{2}}
$$

## Allele intensities revisited

LDA

|  | non T carrier | T carrier |
| :--- | :---: | :---: |
| non T carrier | 46 | 0 |
| T carrier | 0 | 52 |

$$
\mathrm{APER}=\frac{0+0}{46+52}=0
$$

With cross-validation
$E(A E R)=0$

QDA

|  | non T carrier | T carrier |
| ---: | ---: | ---: |
| non T carrier | 46 | 0 |
| T carrier | 0 | 52 |

$$
\mathrm{APER}=\frac{0+0}{46+52}=0
$$

With cross-validation

$$
E(A E R)=0.0102
$$

## Visualisation

## LDA with multiple groups

- The ECM rule can be extended to $k$ groups
- Fisher's discriminant analysis

## ECM rule

ECM rule with $k$ groups (equal costs)
Assign $\mathbf{x}$ to $\pi_{k}$ if

$$
p_{k} f_{k}(\mathbf{x})>p_{i} f_{i}(\mathbf{x}) \quad \forall \quad i \neq k
$$

## Fisher's linear discriminant analysis

- Searches for an optimal linear combination:

$$
Z_{1}=a_{1} X_{1}+a_{2} X_{2}+\cdots+a_{p} X_{p}
$$

- Maximizes the ratio of variability between groups to variability within groups
- Objective function

$$
\frac{a^{\prime} \mathrm{Ba}}{\mathbf{a}^{\prime} \mathbf{W a}}
$$

- $\mathbf{W}$ is the matrix with within-group sums-of-squares
- For a single group $i$

$$
\mathbf{W}_{i}=\left(\mathbf{X}_{i}-\mathbf{1} \mathbf{m}_{i}^{\prime}\right)^{\prime}\left(\mathbf{X}_{i}-\mathbf{1} \mathbf{m}_{i}^{\prime}\right)
$$

- $\mathbf{W}=\sum_{i=1}^{k} \mathbf{W}_{i}$
- $\mathbf{B}$ is the matrix with between-group sums-of-squares
- $\mathbf{T}$ is the matrix with total sums-of-squares

$$
\mathbf{T}=\left(\mathbf{X}-\mathbf{1} \mathbf{m}^{\prime}\right)^{\prime}\left(\mathbf{X}-\mathbf{1} \mathbf{m}^{\prime}\right) \quad \mathbf{T}=\mathbf{W}+\mathbf{B}
$$

## Solution

- The optimal weights are found by solving an eigenvector-eigenvalue problem

$$
\mathbf{W}^{-1} \mathbf{B a}=\lambda \mathbf{a}
$$

- The number of dimensions $d$ in the solution is given by $\min (k-1, p)$

$$
\mathbf{W}^{-1} \mathbf{B A}=\mathbf{A} \mathbf{D}_{\lambda}
$$

- Eigenvectors scaled to satisfy $\mathbf{A}^{\prime} \mathbf{S}_{p} \mathbf{A}=\mathbf{I}$
- Selecting the first two eigenvalues and eigenvectors allows for dimension reduction

## NIST autosomal STR data revisited

The data:

- 29 autosomal STRs
- Consider individuals with African-American, Asian and Caucasian ancestry
- Sample sizes balanced by subsampling

Prior to discriminant analysis:

- STRs coded as binary variables
- Quantification of the data by MDS based on Jaccard metric

Can we predict ancestry from an STR profile?

## STR data in discriminant space

LDA

## Numerical output

|  | 1 | 2 |
| ---: | ---: | ---: |
| Eigenvalue | 550.38 | 194.45 |
| Fraction | 0.74 | 0.26 |
| Cumulative | 0.74 | 1.00 |

|  |  | Principal axis |  |  |  |  |  |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | prior | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
| Afr. Ame. | 0.333 | 0.108 | -0.063 | -0.001 | -0.001 | 0.002 | 0.001 | 0.002 | 0.010 | 0.010 | 0.009 |
| Asian | 0.333 | -0.132 | -0.029 | 0.007 | -0.002 | 0.010 | 0.005 | -0.007 | -0.002 | -0.011 | 0.003 |
| Caucasian | 0.333 | 0.024 | 0.092 | -0.006 | 0.003 | -0.012 | -0.006 | 0.006 | -0.009 | 0.002 | -0.012 |

## Confusion matrix

| LDA |  |  |  |
| ---: | :---: | :---: | :---: |
|  | Afr. Ame. | Asian | Caucasian |
| Afr. Ame. | 86 | 0 | 11 |
| Asian | 1 | 92 | 4 |
| Caucasian | 5 | 6 | 86 |

$\mathrm{APER}=0.093$

| QDA |  |  |  |
| ---: | :---: | :---: | :---: |
|  | Afr. Ame. | Asian | Caucasian |
| Afr. Ame. | 91 | 0 | 6 |
| Asian | 2 | 93 | 2 |
| Caucasian | 5 | 3 | 89 |

$\mathrm{APER}=0.062$

QDA

## More complex...

## Alternative statistical techniques

- An alternative technique for two-group DA is logistic regression
- An alternative technique for multi-group DA is the multinomial logit model
