Session 2: Introduction to Epidemiology and Genetic Epidemiology

ep·i·de·mi·ol·o·gy

/ˌepəˌdēmēˈäləjē/

noun

the branch of medicine that deals with the incidence, distribution, and possible control of diseases and other factors relating to health.

EPIDEMIOLOGY
SCHOOL OF PUBLIC HEALTH

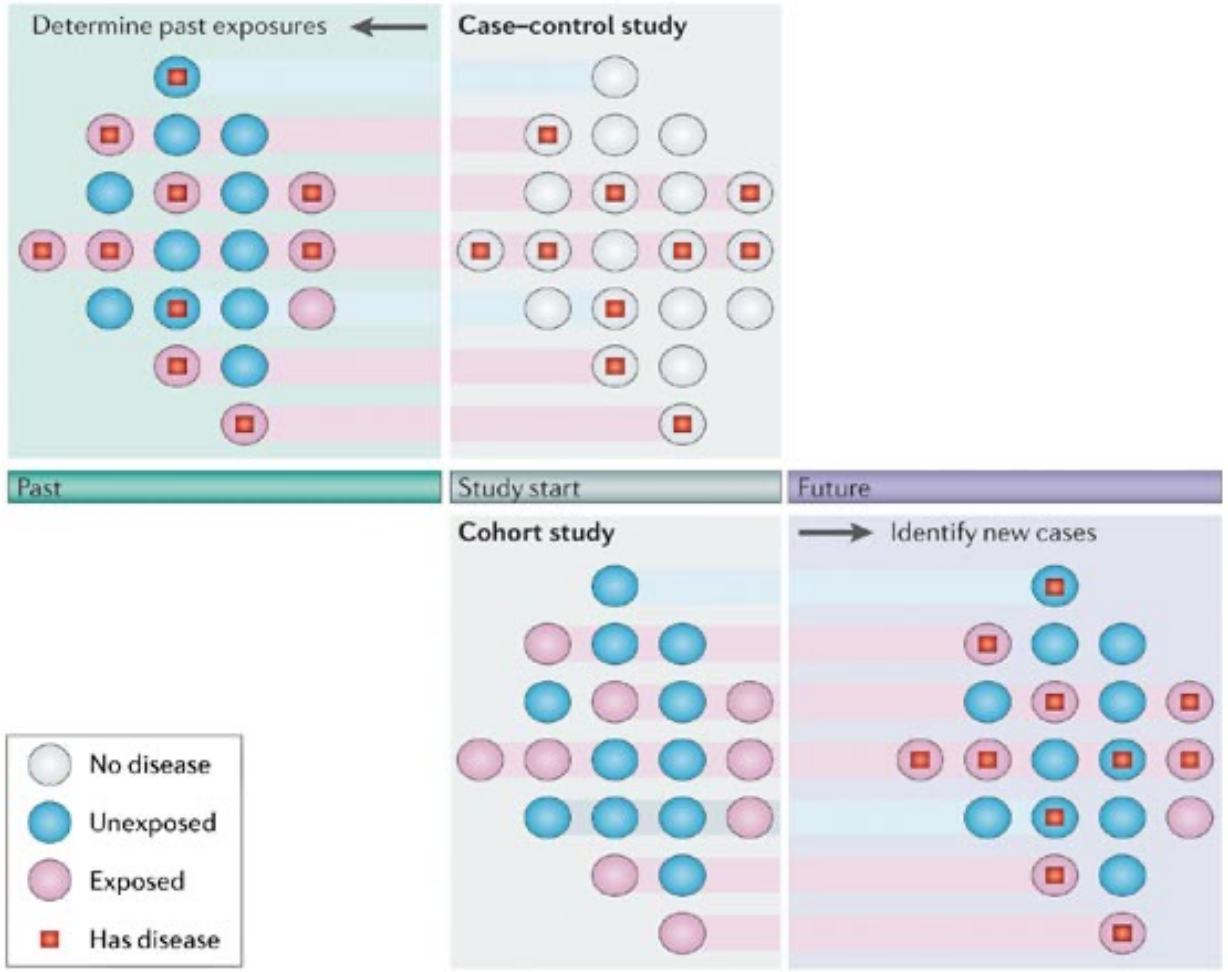
Major goals in Epidemiology

> To obtain an *unbiased & precise* estimate of the true effect of an exposure or intervention on outcome in the population at risk

> To use this knowledge to prevent and treat disease

EPIDEMIOLOGY
SCHOOL OF PUBLIC HEALTH

Cohort vs. case-control studies



Manolio *et al. Nature Reviews Genetics* 2006

Estimated incidence rates in cohorts

Disease incidence per 100,000 per year (%)	Disease examples	Number of incident cases in 5 years for different cohort sizes		
		200,000	500,000	1,000,000
10 (0.01)	Parkinson disease, schizophrenia	91	228	457
50 (0.05)	Colorectal cancer, renal failure	456	1,141	2,282
100 (0.10)	Breast cancer, hip fracture	912	2,279	4,559
200 (0.20)	Diabetes, stroke, heart failure	1,820	4,550	9,100
500 (0.50)	Myocardial infarction, all cancers	4,524	11,309	22,618
3,000 (3.00)	Cataracts, hypertension	25,858	64,644	129,289

Estimated numbers of incident cases available after 5 years of follow-up across the entire age range in the US population are shown, assuming an attrition rate of 3% per year. Data are taken from the Incidence and Prevalence Database.

Manolio. *Nature Reviews Genetics* 2006

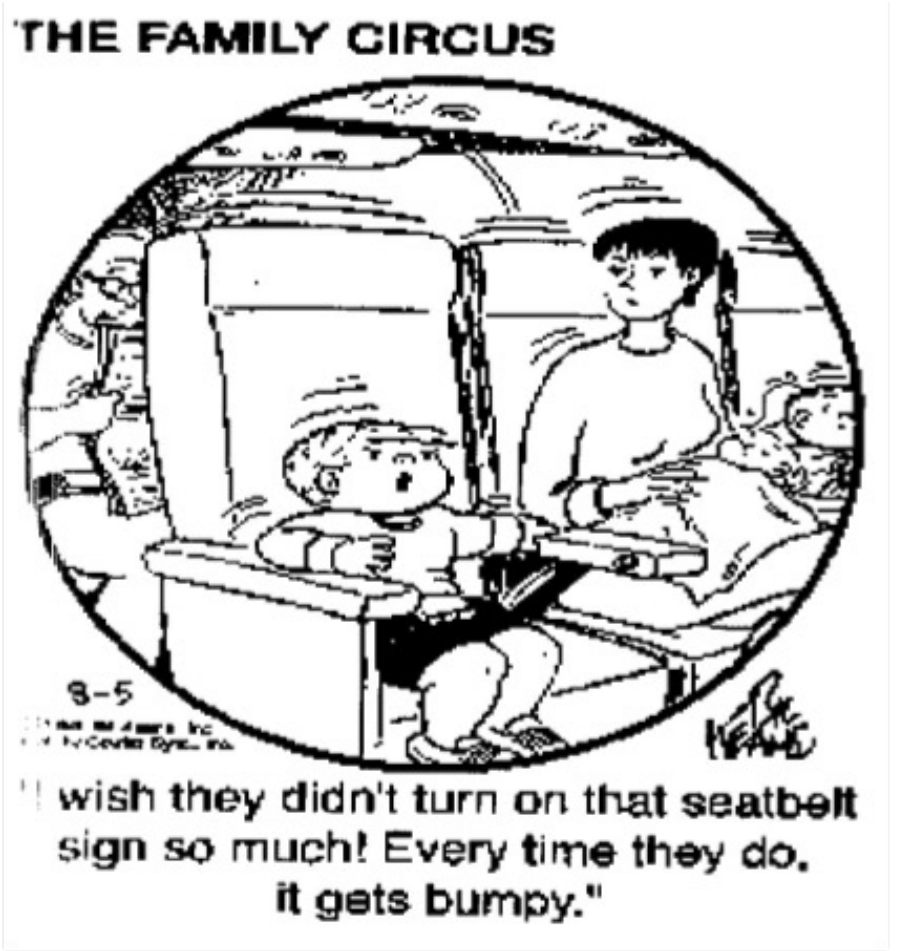
Compared to cohorts, case-control studies are cheap, fast and powerful

However, case-control studies suffer from several drawbacks:
the need to identify appropriate controls
they are more sensitive to recall bias

Association and Causality

> An exposure and outcome are *associated* if there is a differential distribution:
  - The prevalence of exposure differs between cases and controls.

> An exposure is *causal* for the outcome if the presence (or absence) of the exposure directly or indirectly influences whether the outcome occurs.



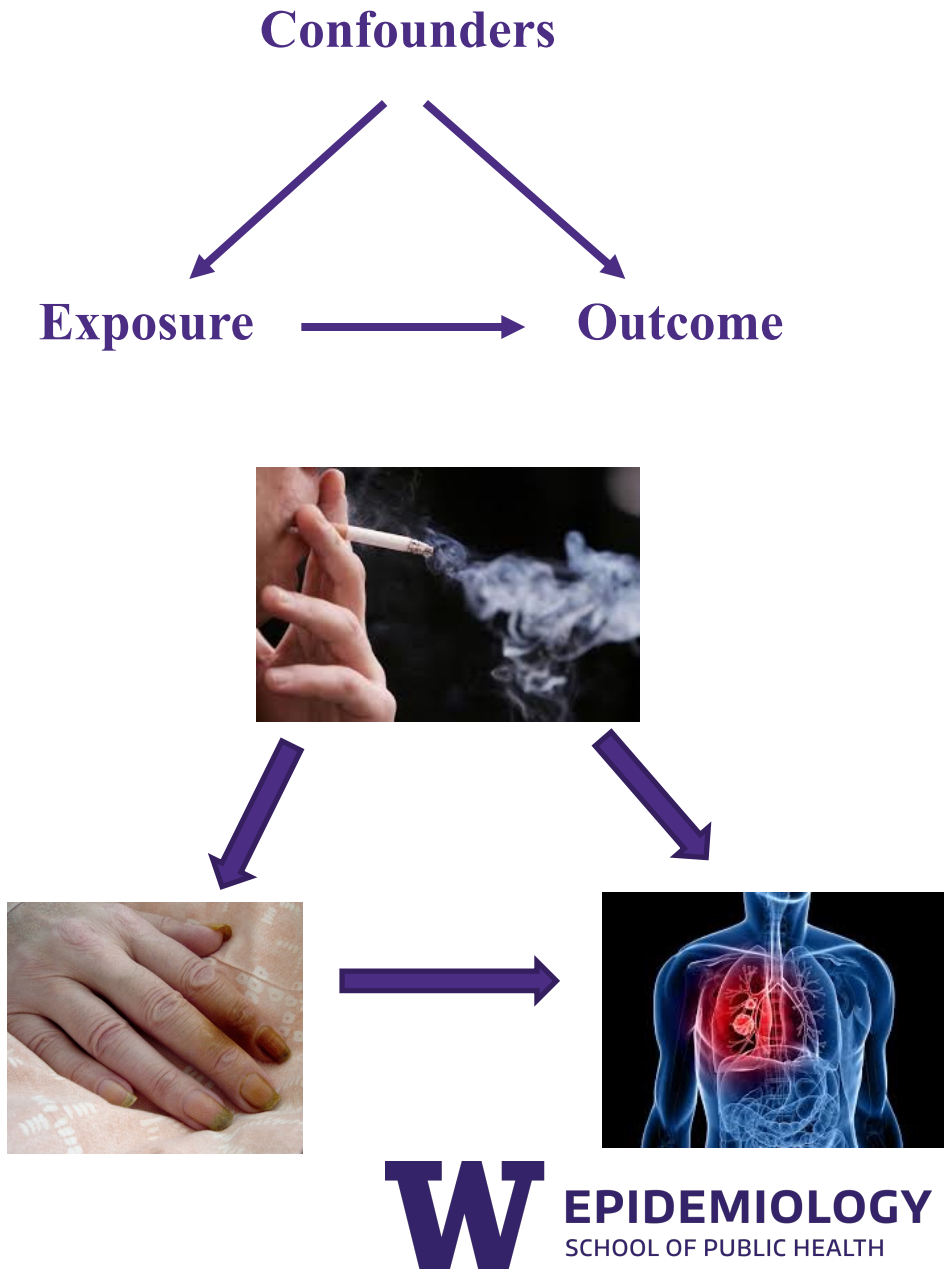
Sources of bias in epidemiology

- **Selection Bias**
  - Arises when cases and controls are coming from different source populations (e.g., pediatric cases, adult controls)
- **Survival bias**
  - When cases are recruited some time after they were diagnosed. Might lead to a milder form of disease. This is especially true for aggressive/fatal disease (e.g., pancreatic cancer, heart attack)
- **Diagnostic bias**
  - If the investigator determining the outcome knows whether the person was exposed or not to the risk factor under study (e.g., if the radiologist knows that a potential pulmonary disease patient smokes, they may look more carefully at the x-ray).
- **Recall bias**
  - Accuracy and completeness of exposures, life-style behaviors,… (e.g., cases might be more motivated to complete a questionnaire accurately).

Confounding

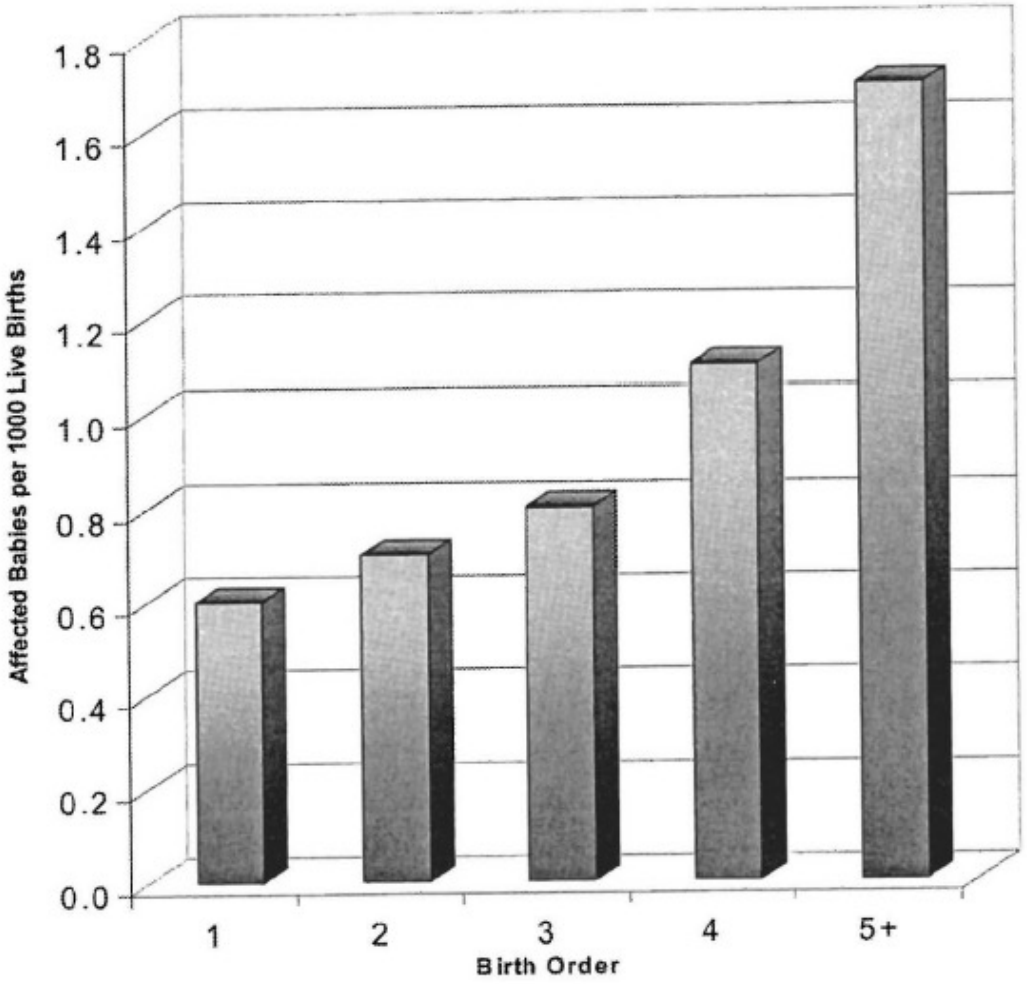
- **A confounder is often defined as a factor that is:**
  1. A risk factor for the disease
  2. Associated with the exposure
  3. Not a direct result of the exposure

- **Confounding can lead to false positive findings.**



BREAKOUT ACTIVITY

Confounding example: Birth order and Down syndrome



Data from Stark and Mantel (1966)

Source: Rothman 2002

1. Can you think of a factor that would confound the observed association?

2. How can you use data on your proposed confounding factor to reassess the association between birth order and Down Syndrome?

3. Can you think of potential confounders in genetic epidemiology?

Loren Capelli

MY MOTHER fought cancer for almost a decade and died at 56. She held out long enough to meet the first of her grandchildren and to hold them in her arms. But my other children will never have the chance to know her and experience how loving and gracious she was.

We often speak of "Mommy's mommy," and I find myself trying to explain the illness that took her away from us. They have asked if the same could happen to me. I have always told them not to worry, but the truth is I carry a "faulty" gene, BRCA1, which sharply increases my risk of developing breast cancer and ovarian cancer.

NATIONAL CANCER INSTITUTE
CHANCES OF DEVELOPING BREAST CANCER BY AGE 70

Specific inherited mutations in the BRCA1 and BRCA2 genes increase the risk of breast and ovarian cancers. Testing for these mutations is usually recommended in women without breast cancer only when the person's individual or family history suggests the possible presence of a harmful mutation in BRCA1 or BRCA2. Testing is often recommended in younger women newly diagnosed with breast cancer because it can influence treatment decisions and have implications for their family members.

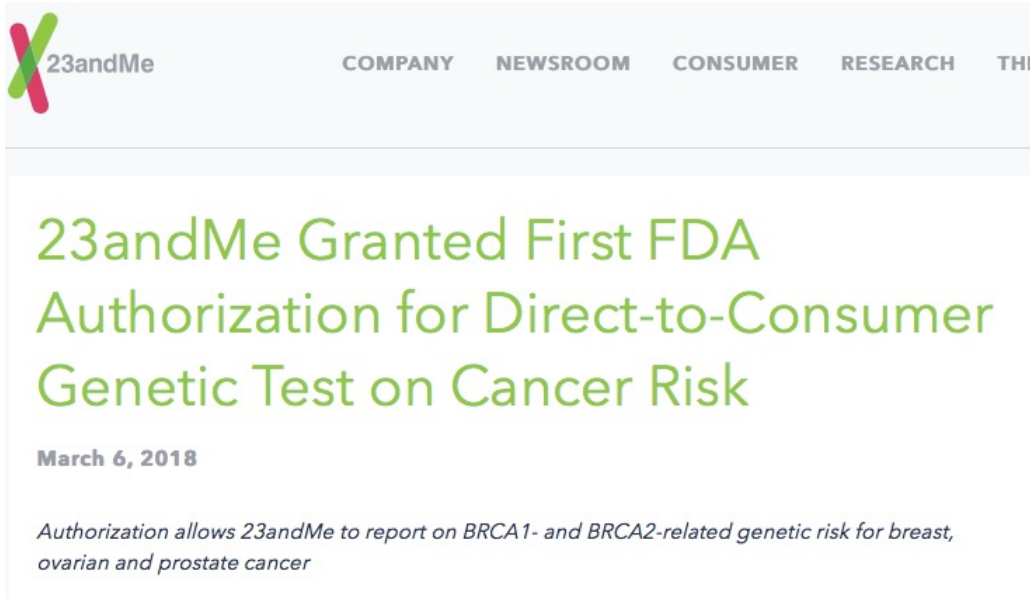
Genetic testing of *BRCA1 and BRCA2 in the population*



23andMe COMPANY NEWSROOM CONSUMER RESEARCH TH

23andMe Granted First FDA Authorization for Direct-to-Consumer Genetic Test on Cancer Risk

March 6, 2018

Authorization allows 23andMe to report on BRCA1- and BRCA2-related genetic risk for breast, ovarian and prostate cancer

What to know about: BRCA1/BRCA2 (Selected Variants) and our test

Specific genetic variants in the BRCA1 and BRCA2 genes are associated with an increased risk of developing certain cancers, including breast cancer (in women and men) and ovarian cancer. These variants may also be associated with an increased risk for prostate cancer and certain other cancers. This test includes three genetic variants in the BRCA1 and BRCA2 genes that are most common in people of Ashkenazi Jewish descent.

BRCA1- and BRCA2-associated cancer risks

- Women with a variant have a 45-85% chance of developing breast cancer by age 70 and up to a 46% chance of developing ovarian cancer by age 70.
- Men with a variant have up to an 8% lifetime risk of developing male breast cancer and may have an increased risk for prostate cancer.
- Men and women with a variant may also have an increased risk for pancreatic cancer and melanoma.
- Learn more about these cancer risks

Other factors that affect cancer risk

- Age
- Family history
- Obesity
- Lifestyle factors

When cancers develop

In general, the chances of developing cancer increase as a person gets older. However, women with a BRCA1 or BRCA2 variant have an increased risk for early-onset breast cancer. Men with a variant may develop earlier and more aggressive prostate cancer.

What do we test?

- We test for three specific genetic variants: the **185delAG** and **5382insC** variants in the BRCA1 gene and the **6174delT** variant in the BRCA2 gene. These variants are associated with an increased risk of developing certain cancers.
- We do not test for all possible variants in the BRCA1 and BRCA2 genes. More than 1,000 variants in these genes are known to increase cancer risk.
- This test does not include variants in other genes linked to hereditary cancers.
- Genetic testing for BRCA1 and BRCA2 variants in the general population is not currently recommended by any healthcare professional organizations.

Important ethnicities

- The three variants included in this test are most commonly found in people of **Ashkenazi Jewish** ⓘ descent.
- In 23andMe customers of other ethnicities, between 0% and 0.1% of individuals has one of the three variants in this report.
- This test does **not** include most of the BRCA1 and BRCA2 variants found in people of other ethnicities. Therefore, a "variants not detected" result is less informative for people with no Ashkenazi Jewish ancestry.

HDL ("Good") Cholesterol and Myocardial Infarction (MI)

↑ HDL -> ↓ MI risk

Increasing HDL concentrations might help decrease cardiovascular disease risk.

EPIDEMIOLOGY
SCHOOL OF PUBLIC HEALTH

People who carry gene variants that increase HDL do not have a lower risk of MI

Since HDL is correlated with exercise, weight loss, diet (nuts, fish) it is likely that these lower your risk for MI rather than HDL itself
